Security in BeyondTrust Remote Support (On-Premises)

The purpose of this document is to help technically-oriented professionals understand the security-related value BeyondTrust Remote Support can bring to your organization. Remote Support can help your support organization stay secure and compliant, while improving the efficiency and success of your organization with a better end-user support experience.

BeyondTrust Remote Support Overview

BeyondTrust connects and protects people and technology with leading secure access solutions that strengthen security while increasing productivity. The BeyondTrust Appliance B Series gives support technicians secure remote control of computers, over the internet or on local networks. This specialized B Series Appliance provides exceptional performance, reliability, ease-of-use, and scalability through a solution that is optimized for remote support. With BeyondTrust Remote-Support, a support technician can see the supported screen and control the supported system remotely, as if physically present.

Using multiple features designed to ensure the security of remote support sessions, Remote-Support integrates with external user directories, such as LDAP, for secure user management; prevents sensitive data from being routed outside the organization; and supports extensive auditing and recording of support sessions. Logging is performed by the B Series Appliance, which allows for the review of all customer and support representative interactions, including video playback of all desktop screen interactions. Remote-Support also integrates with leading systems management and identity management solutions and includes an API for deeper integration. With Remote-Support, support managers can create support teams, customize queues, and report on all support activity.

Remote-Support enables remote access to multiple operating systems, including Windows, Mac, various Linux distributions, and mobile operating systems. Remote-Support also enables remote control of various kinds of systems, including laptops, desktops, servers, kiosks, point-of-sale systems, smartphones, and network devices.

Remote-Support can work over internal and extended networks, or it can be internet-accessible. This allows support organizations to avoid less effective means of support by driving requests through custom support portals hosted on a hardened B Series Appliance. Remote-Support can match support requests with the appropriate technician or team. Remote-Support then mediates connections between customers and support representatives, allowing chat sessions, file uploads and downloads, remote control of desktops, screen-sharing in either direction, running of presentations, and access to system information and diagnostics.

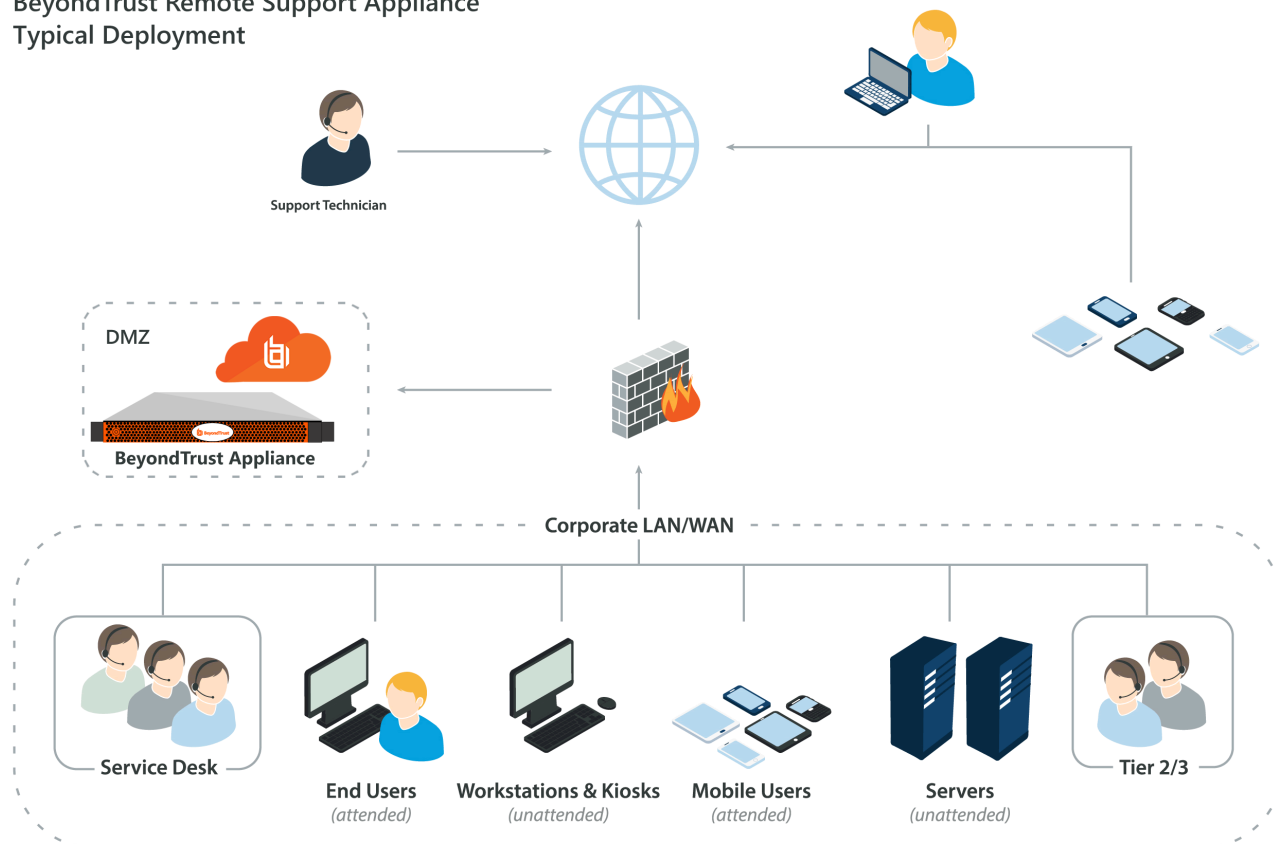

Architecture of Remote Support (On-Premises)

To make secure remote support possible, the BeyondTrust Remote-Support architecture places the BeyondTrust Appliance B Series as the focal point of all communications. The B Series Appliance provides a platform to build a support portal, a site through which an organization funnels all remote support requests. The support portal offers a web site interface using Hypertext Transfer Protocol (HTTP) for unauthenticated services, Secure HTTP (HTTPS) for authenticated services, and direct client connections accepted over a proprietary, BeyondTrust-defined protocol.

The B Series Appliance is comprised of two main components. The first, called Base, is made up of the firmware that provides system-level configuration of a B Series Appliance. Settings such as IP addresses and security certificate configurations are all configured via the Base firmware, which is accessed via the /appliance web interface.

The software used for site-level configuration, accessed via the /login web interface, makes up the second functional component. The user configuration and session options take place behind the /login page, and you can download the representative console, endpoint client, Jump Clients, Jumpoints, and security provider connection agents from there. Sessions always occur through the B Series Appliance, and since the connections are outbound from the clients to the B Series Appliance using well known ports, the application can communicate without local firewall changes.

BeyondTrust Remote Support Appliance Typical Deployment

Validation

To ensure the security and value of our product, BeyondTrust incorporates vulnerability scanning in our software testing process. We track the results of vulnerability scans performed prior to a software release and prioritize resolution based on severity and criticality of any issues uncovered. Should a critical or high-risk vulnerability surface after a software release, a subsequent maintenance release addresses the vulnerability. Updated maintenance versions are distributed to our customers via the update manager interface within the Remote Support administrative interface. When necessary, BeyondTrust Support contacts customers directly, describing special procedures to follow to obtain an updated maintenance version.

In addition to internal scanning procedures, BeyondTrust contracts with third-parties for a source code level review as well as penetration testing. The source code review conducted essentially provides validation from a third party that coding best practices are followed and that proper controls are in place to protect against known vulnerabilities. A penetration test is conducted to confirm the findings.

Authentication to BeyondTrust Remote Support (On-Premises)

Remote Support can be provisioned for locally defined user Remote Support accounts or can be integrated into existing authentication sources. For instance, a commonly integrated authentication source is Microsoft Active Directory. When using a directory such as this, all authentication follows the existing controls and processes in place for safeguarding user accounts.

Additional security providers are available that allow for representative authentication using Kerberos or SAML (for single sign-on) or using RADIUS (for multi-factor authentication). Each of these providers can be configured to use LDAP groups to set the permissions for the support representative, allowing you to map existing LDAP groups to support teams in Remote Support.

There are a large number of granular permissions that can be granted to support representatives. These permissions determine which features in Remote Support a representative has access to and can require end-user prompting so that the user receiving support must approve representative actions.

Credential Management in BeyondTrust Remote Support (On-Premises)

BeyondTrust Remote Support can be integrated with an Endpoint Credential Manager (ECM) to improve password security for representatives, privileged users, and vendors.

An ECM functions as the middleware for communication, and the ECM can be used to integrate Remote Support with third-party password vaults as well as with BeyondTrust Privileged Identity.

 For more information about BeyondTrust Privileged Identity, formerly RED IM, please see [BeyondTrust Privileged Identity](https://www.beyondtrust.com/docs/privileged-identity/index.htm) at <https://www.beyondtrust.com/docs/privileged-identity/index.htm>.

 **Note:** The ECM is not required when using BeyondTrust Vault, the credential store on the B Series Appliance.

Credential injection is a built-in feature of Remote Support. It allows administrators, representatives, and other privileged users to seamlessly inject credentials into systems without exposing plain text passwords, and this feature can also be used with third-party vault tools.

Credential Management with BeyondTrust Vault

BeyondTrust Vault is a credential store that exists on the B Series Appliance, enabling discovery of and access to privileged credentials. You can manually add privileged credentials, or you can use the built-in discovery tool to scan and import Active Directory and local accounts into BeyondTrust Vault.

BeyondTrust Vault fits seamlessly with service desk workflow because it is integrated directly with the Remote Support solution. Technicians do not have to learn to use another tool or even exit Remote Support to retrieve passwords. With just one click in the BeyondTrust representative console, users can select the correct credential from the dropdown and log directly in to a remote system - without ever having to know or even see the actual password.

Frequently Asked Questions about BeyondTrust Vault

What Communication Pathways Are Used With BeyondTrust Vault (Ports, Protocols, Connection Types, etc.)?

- **Active Directory and Discovery:**
 - By default, discovery occurs over LDAP via the Active Directory Service Interface (ADSI) on port 389.
 - If LDAPS is enabled, Active Directory queries run over LDAP under an SSL/TLS layer on port 636, unless another port is specified. This transport-layer security encrypts all data communicated to and from Active Directory.
- **Windows Local Discovery**
 - Local Windows accounts are discovered via a series of calls directly to Windows APIs.
 - These APIs use Remote Procedure Calls (RPCs) and named pipes as the network protocol.
 - The RPC process translates the request parameters as well as any response data into a standard, encoded format for

transmission.

- Protection is negotiated at the operating system level.

Where Does Encryption for BeyondTrust Vault Occur?

- Passwords and private SSH keys are encrypted at rest using AES-256-GCM in addition to any full disk encryption enabled for the BeyondTrust Appliance B Series.
- Passwords and private SSH keys are encrypted in transit using an ephemeral public+private key pair when used for injection. This encryption occurs in addition to Remote Support's use of TLS to encrypt communication among all Remote Support components, such as the B Series Appliance, Jumpoint, customer client, etc.
- Passwords are encrypted in transit by TLS.
- Passwords used by Jumpoints to authenticate with Active Directory are never sent in plaintext to Active Directory.

Where Is the Vault Encryption Key Stored? Can It Be Accessed via /login or /appliance?

- The Vault encryption key is needed to decrypt credentials managed by BeyondTrust Vault. This key is stored in one of the credential stores configured on the appliance.
- The encryption key can be backed up by going to **/login > Management > Software Management > Backup Vault Encryption Key**. The backup file format used for the encryption key is the same NSB file format used for configuration and reporting data.

Is the Remote Support Application Database Encrypted, and If So, How?

- BeyondTrust Vault stores data in an encrypted format in the database. If full disk encryption is enabled for your B Series Appliance, the Remote Support application database is also encrypted. However, this is independent of the encryption performed by BeyondTrust Vault.

What Best Practices Are Recommended to Maintain the Highest Level of Security Across All Points of Connection (Discovery, Injections, Support, etc.)?

- BeyondTrust recommends using a valid CA-signed SSL certificate to protect communication among all Remote Support components.
- We recommend that Jumpoints run on a system only a few privileged users have permissions to access.

 For more information about Jumpoints, please see [Remote Support Jumpoint Guide: Unattended Access to Computers in a Network](https://www.beyondtrust.com/docs/remote-support/how-to/jumpoint/index.htm) at <https://www.beyondtrust.com/docs/remote-support/how-to/jumpoint/index.htm>.

 **Note:** There are no user-visible security settings for BeyondTrust Vault.

Encryption and Ports in BeyondTrust Remote Support (On-Premises)

BeyondTrust Remote Support can be configured such that it enforces the use of SSL for every connection made to the B Series Appliance. Remote Support requires that the SSL certificate being used to encrypt the transport is valid.

Remote Support can natively generate certificate signing requests. It also supports importing certificates generated off the B Series Appliance. Configuration options also are available to disable the use of SSLv3, TLSv1, and/or TLSv1.1. BeyondTrust always has TLSv1.2 enabled to ensure proper operation of the B Series Appliance. Available cipher suites can be enabled or disabled and reordered as needed to meet the needs of your organization.

The BeyondTrust software itself is uniquely built for each customer. As part of the build, an encrypted license file is generated that contains the support portal Domain Name System (DNS) name and the SSL certificate, which is used by the respective Remote Support client to validate the connection that is made to the B Series Appliance.

The chart below highlights the required ports and the optional ports. Note that there is very minimal port exposure of the BeyondTrust Appliance B Series. This drastically reduces the potential exposed attack surface of the B Series Appliance.

Firewall Rules	
Internet to the DMZ	
TCP Port 80 (optional)	Used to host the portal page without the user having to type HTTPS. The traffic can be automatically rolled over to port 443.
TCP Port 443 (required)*	Used for all session traffic.
UDP Port 3478 (optional)	Used to enable Peer-to-Peer connections if the Use Appliance as Peer-to-Peer Server option is selected.
Internal Network to the DMZ	
TCP Port 80 (optional)	Used to host the portal page without the user having to type HTTPS. The traffic can be automatically rolled over to port 443.
TCP Port 161/UDP	Used for SNMP queries via IP configuration settings in the /appliance interface.
TCP Port 443 (required)*	Used for all session traffic.
DMZ to the Internet	
TCP Port 443 to the specific host gwsupport.bomgar.com (optional)	Default port used to establish connections with BeyondTrust Support for advanced troubleshooting/repairs.
TCP Port 443 to the specific host btupdate.com (optional)	You can optionally enable access from the B Series Appliance on port 443 to this host for automatic updates, or you can apply updates manually.
DMZ to the Internal Network	
UDP Port 123	Access NTP server and sync the time.
LDAP - TCP/UDP 389 (optional)‡	Access LDAP server and authenticate users.
LDAP - TCP/UDP 636 (optional)‡	Access LDAP server and authenticate users via SSL.
Syslog - UDP 514 (required for logging)	Used to send syslog messages to a syslog server in the internal network. Alternatively, messages can be sent to a syslog server located within the DMZ.
Syslog - TCP Port 6514	Used to send syslog messages over TLS to a syslog server in the internal network. Alternatively, messages can be sent to a syslog server located within the DMZ.
DNS - UDP 53 (required if DNS server is outside the DMZ)	Access DNS server to verify that a DNS A record or CNAME record points to the B Series Appliance.

Firewall Rules	
TCP Port 25, 465, or 587 (optional)	Allows the B Series Appliance to send admin mail alerts. The port is set in SMTP configuration.
TCP Port 443 (optional)	B Series Appliance to web services (e.g., HP Service Manager, BMC Remedy) for outbound events.
TCP Port 5696	Allows the B Series Appliance to access the KMIP server located in the internal network for Data at Rest Encryption.
Internal Network to Internal Network	
Port 389, 636 (Active Directory), 445 (Local Account Management)	Ports used for discovery and rotation of Vault accounts.

*Each of the following BeyondTrust components can be configured to connect on a port other than 443: representative console, customer client, presentation attendee client, Jumpoint, connection agent.

‡ If the LDAP server is outside of the DMZ, the BeyondTrust Connection Agent is used to authenticate users via LDAP.

Auditing of BeyondTrust Remote Support (On-Premises)

Logging and Storage

BeyondTrust Remote Support provides two types of support session logging. All the events of an individual support session are logged as a text-based log. This log includes representatives involved, permissions granted by the customer, chat transcripts, system information, and any other actions taken by the Remote Support representative. This data is available on the B Series Appliance in an uneditable format for up to 90 days, but it can be moved to an external database using the Remote Support API or the Remote Support Integration Client (IC). All support sessions are assigned a unique session ID referred to as an LSID. The session LSID is a 32-character string that is a unique GUID for each session. The LSID is stored as part of each session log for every session conducted.

Remote Support also allows enabling video session recordings. This records the visible user interface of the customer screen for the entire screen sharing session. The recording also contains metadata to identify who is in control of the mouse and keyboard at any given time during the playback of the recorded session. The period of time these recordings remain available depends on the amount of session activity and the available storage, up to 90 days maximum. As with the support session logging, these recordings can be moved to an external file store using the API or the IC.

Each B Series Appliance model has a certain amount of available disk space. If this space becomes filled, the oldest data is automatically deleted, even if the number of days set to keep logging data has not been reached. The IC can be used to export data off the B Series Appliance and store it if needed to comply with security policies. Remote Support can also be configured to store data for a shorter period of time to help comply with security policies.

BeyondTrust Integration Client

The Remote Support Integration Client (IC) is a Windows application that uses the Remote Support API to export session logs, recordings, and backups from one or more B Series Appliances according to a defined periodic schedule. The IC uses plug-in modules to determine the repository for the exported data.

Remote Support provides two IC plug-in modules. One handles export of reports and video recordings to a file system destination. The second exports select report information (a subset of the entire data collection) to a Microsoft SQL Server database. Setup of the IC for SQL Server includes all of the procedures needed to automatically define the necessary database, tables, and fields.

In practice, the IC is used to export support session data that must be retained for legal and compliance reasons. The reports and recordings are archived in a file system, indexed by the B Series Appliance and session IDs. Data stored in the SQL Server tables may be queried to locate the Remote Support session ID corresponding to given search criteria such as date, representative, or IP address.

All authentication events, such as when a representative logs into the representative console or accesses the /login or /appliance web interface, generate a syslog event which can be logged on a syslog server. Additionally, any configuration change that is made to the B Series Appliance also generates a syslog event showing the change that was made and by which user. If the syslog configuration itself is ever modified, it results in an administrative email sent by the B Series Appliance to the configured administrative email account for the B Series Appliance.
